#### Abstract

It is proposed that lepton number conservation, purely left-handed charged weak currents and vanishing neutrino masses are a limitıng case of a parity symmetric $\mathrm{SU} 2_{\mathrm{L}} \times \mathrm{SU}_{\mathrm{R}} \times \mathrm{U} 2{ }^{\mathrm{V}}$ gauge theory. Right-handed neutrinos acquire a lepton number volating mass, leaving an $\mathrm{SU} 2_{\mathrm{L}} \times \mathrm{U} 1$ subgroup unbroken. Consequences for the decay $\mu \rightarrow \mathrm{e} \gamma$ are studied.

In a gauge theory of weak and associated interactions (electromagnetic, strong, ...) in which parity and tume reversal are spontaneously broken discrete symmetries, on an equal footing with the continuous symmetries of $\operatorname{SU} n$ (fermions) $\times$ SU $n$ (fermions) corresponding to chiral substitutions of lepton and quark flavors respectively, the following features particular to leptons are intrinsically related:
(i) Neutrino masses are nonvanishing but orders of magnitude are smaller than charged lepton masses ${ }^{\ddagger 1}$ [1].
(ii) Considerng the mass scale set by $G_{\mathrm{F}}^{-1 / 2} \approx 300 \mathrm{GeV}$ as small compared to the mass scale on which parity unvariance is restored, the chiral structure of the (light) neutrinos determines the corresponding (lowest level) gauge group to be $\left((\mathrm{SU} 2)_{\mathrm{L}} \times \mathrm{U} 1\right)$ [3].
(iii) Right-handed leptons (and quarks) are singlets with respect to (SU2 ${ }_{L}$ ) [3]. (Scalars generating the masses of the charged leptons transform as doublets under $\mathrm{SU} 2_{\mathrm{L}}$.)
(iv) Lepton numbers ( $L_{\mathrm{e}}, L_{\mu}, L_{\mathrm{e}}+L_{\mu}$ ) are not exactly conserved [4-6]. We study a scheme for leptons in which the breakdown of parity is reflected by the sequence of gauge groups

$$
\begin{equation*}
\underbrace{\mathrm{SU} 2_{\mathrm{L}} \times \mathrm{SU} 2_{\mathrm{R}} \times(\mathrm{U} 1)^{\mathrm{V}} \rightarrow \mathrm{SU} 2_{\mathrm{L}} \times(\mathrm{U} 1) . . . . . .}_{\text {SO4 }} \tag{1}
\end{equation*}
$$

We will investigate the consequences for the decays

$$
\begin{equation*}
\mu \rightarrow \mathrm{e}^{\gamma}(\mu \rightarrow 3 \mathrm{e}) . \tag{8}
\end{equation*}
$$

An irreducible (lepton) multiplet (one electronlike, one muonlike,...) can be represented alternatively by 4 Majorana fields or 4 (e.g.) left-handed fields (including CPT-conjugate fields):

In eq. (2) $\psi_{A}^{(k)}\left(k_{1} A=1, \ldots, 4\right)$ denote hermitian (four component) Majorana fields, ( $\ell_{\mathrm{L}}$ denote left-handed, com-

[^0]plex two component fields $\left(\dot{\alpha}=1,2 ; \ell=\nu_{\mathrm{e}}, \widetilde{\mathrm{N}}_{\mathrm{e}}, \mathrm{e}^{-}, \widetilde{\mathrm{e}}^{+}\right.$and $\epsilon^{\dot{\alpha} \dot{\beta}} \equiv\left(\begin{array}{c}0 \\ 1\end{array}-\frac{1}{0}\right)^{\ddagger 3}$. The (U1) weak hypercharge $Y_{\mathrm{V}}$ takes on the values -1 for $\left(\nu_{\mathrm{e}}, \mathrm{e}^{-}\right)_{\mathrm{L}} ;\left(\mathrm{N}_{\mathrm{e}}, \mathrm{e}^{-}\right)_{\mathrm{R}}$ in order to satisfy the relation

$$
\begin{equation*}
Q^{\mathrm{e} . \mathrm{m} .}=I_{3}^{\mathrm{L}}+I_{3}^{\mathrm{R}}+\frac{1}{2} Y_{\mathrm{V}} \tag{3}
\end{equation*}
$$

and thus can be identified with $(-1)$ lepton number ${ }^{\neq 4}$.
Yukawa couplings can only involve scalar multiplet transforming like the symmetric product of two spinor representations of SO4, i.e. the multiplets

$$
\begin{equation*}
\varphi_{\mathrm{L}}: \quad(3,1, \pm 2), \quad \varphi_{\mathrm{R}}: \quad(1,3 ; \mp 2), \quad \varphi_{\mathrm{LR}}: \quad(2,2 ; 0) . \tag{4}
\end{equation*}
$$

In eq. (4) the first two numbers denote the values of $\left(2 J_{\mathrm{L},(\mathrm{R})}+1\right)$ characterizing the $\mathrm{SU} 2_{\mathrm{L}, \mathrm{R}}$ multiplets and the third number gives the value of $Y_{V}$.

The multiplicities of the representations in eq. (4) occurring in the scalar sector are of physical signficance. They determine the range of Yukawa interactions beyond the couplings of the Goldstone mode scalars to fermions. These "genuine" Yukawa interactions will in general violate at least some of the conservation laws valid for the (incomplete) interactions of fermions and gauge bosons [10].

The hierarchy of gauge groups (1) extended to include the quarks (left-handed doublets, right-handed singlets)

$$
\begin{equation*}
\binom{u}{d^{\prime}}_{L}\binom{c}{c^{\prime}}_{L} ; \quad(u, d, c, s)_{R} ; \quad d_{L}^{\prime}=\cos \vartheta_{c} d+\sin \vartheta_{c} s, \quad s_{L}^{\prime} \perp d_{L}^{\prime} \tag{5}
\end{equation*}
$$

would imply the following unacceptable mass matrix provided only one multiplet $\varphi_{\text {LR }}(2,2 ; 0)$ would generate all quark masses:

$$
\begin{equation*}
m_{\mathrm{u}} / m_{\mathrm{d}}=m_{\mathrm{c}} / m_{\mathrm{s}} ; \quad \vartheta_{\mathrm{c}}=0 \tag{6}
\end{equation*}
$$

We conclude that there are several scalar multiplets transforming like $\varphi_{\mathrm{LR}}(2,2,0)$ and consider for simplitiy two such multiplets coupling to the leptons together with two multiplets transforming like $\varphi_{R}(1,3,-2)$ and $\varphi_{L}(3,1$, -2 ) (and their antiparticles):

$$
\begin{array}{ll}
\varphi_{\mathrm{LR}}: & \mathrm{a}_{\rho \sigma}=\left(\begin{array}{ll}
\mathrm{a}_{1} & \mathrm{a}^{+} \\
\mathrm{a}^{-} & \mathrm{a}_{2}
\end{array}\right) ;
\end{array} \mathrm{a}_{\rho \sigma}^{*} ; \quad \mathrm{b}_{\rho \sigma}=\left(\begin{array}{ll}
\mathrm{b}_{1} & \mathrm{~b}^{+} \\
\mathrm{b}^{-} & \mathrm{b}_{2} \tag{7}
\end{array}\right), \quad \mathrm{b}_{\rho \sigma}^{*} .
$$

$\mathrm{a}_{1,2}, \mathrm{~b}_{1,2}, \mathrm{~d}_{0}, \mathrm{~S}_{0}$ are electrically neutral but not self-conjugate; $\mathrm{d}^{+}, \mathrm{s}^{+}$singly and $\mathrm{d}^{++}, \mathrm{s}^{++}$doubly charged. The interaction of the scalars in (7) with the electron and muon multiplets ${ }^{\ddagger 5}$ are:

[^1]$\mathcal{H}_{\mathrm{Y}}=\left\{\begin{array}{l}\bar{\ell}_{\rho}^{(i)}\left[h_{1}^{i k} \mathrm{a}_{\rho \sigma}+h_{2}^{i k_{\mathrm{b}}} \mathrm{b}_{\rho \sigma}\right] \frac{1+\gamma_{5}}{2} \ell_{\sigma}^{(k)} \\ \ell_{\rho \mathrm{R}}^{(i)} \frac{1}{2} h_{\mathrm{R}}^{i k} \mathrm{~d}_{\rho \sigma} \ell_{\sigma \mathrm{R} \alpha}^{(k)} \\ \ell_{\rho \mathrm{L}_{\beta}}^{(i)} \frac{1}{2} h_{\mathrm{L}}^{i k} \mathrm{~S}_{\rho \sigma} \ell_{\sigma \mathrm{L}}^{(k)}{ }_{\beta}\end{array}\right\}+$ h.c.

$$
\begin{equation*}
\ell_{1}^{(1)}=\left(\nu_{\mathrm{e}}, \mathrm{~N}_{\mathrm{e}}\right) ; \quad \ell_{2}^{(1)}=\mathrm{e}^{-} ; \quad \ell_{1}^{(2)}=\left(\nu_{\mu}, \mathrm{N}_{\mu}\right) ; \quad \ell_{2}^{(2)}=\mu^{-} \tag{8}
\end{equation*}
$$

Spontaneous symmetry breaking is induced by the vacuum expectation values

$$
\langle\mathrm{a}\rangle_{0}=\left(\begin{array}{ll}
A_{1} & 0  \tag{9}\\
0 & A_{2}
\end{array}\right), \quad\langle\mathrm{b}\rangle_{0}=\left(\begin{array}{cc}
B_{1} & 0 \\
0 & B_{2}
\end{array}\right), \quad\langle\mathrm{d}\rangle_{0}=\left(\begin{array}{cc}
D & 0 \\
0 & 0
\end{array}\right), \quad\langle\mathrm{s}\rangle_{0}=\left(\begin{array}{cc}
S & 0 \\
0 & 0
\end{array}\right)
$$

We may assume $A_{1}, A_{2}, B_{1}, D$ real, nonnegatıve without loss of generality. The breakdown $\mathrm{SU} 2_{\mathrm{L}} \times \mathrm{SU} 2_{\mathrm{R}} \times \mathrm{U} 1_{\mathrm{V}}$ $\rightarrow \mathrm{SU} 2_{\mathrm{L}} \times(\mathrm{U} 1)$ correspond to $D \neq 0$ only.

Points (1)-(iv) become indeed logically connected if we choose

$$
\begin{equation*}
S \approx 0 ; \quad\left(A_{1,2} ; B_{1,2}\right)=\mathrm{O}\left(G_{\mathrm{F}}^{-1 / 2}\right) ; \quad\left(A_{1,2} ; B_{12}\right) \ll D \tag{10}
\end{equation*}
$$

The mass matrix in the charged lepton sector $\mathscr{M}_{\mathrm{ch}}$ is independent of $D$ and it serves to define the basic fields with respect to which $m_{c h}$ is diagonal

$$
\begin{equation*}
\binom{\nu_{\mathrm{e}}}{\mathrm{e}^{-}}_{\mathrm{L}}, \quad\binom{\nu_{\mu}}{\mu^{-}}_{\mathrm{L}} ; \quad\binom{\mathrm{N}_{\mathrm{e}}}{\mathrm{e}^{-}}_{\mathrm{R}}, \quad\binom{\mathrm{~N}_{\mu}}{\mu^{-}}_{\mathrm{R}} \tag{11}
\end{equation*}
$$

In the above basis the mass matrices in the neutral and charged lepton sectors are, before $D$ is turned on

$$
m_{\mathrm{n}}=A_{1} h_{1}+B_{1} h_{2} ; \quad m_{\mathrm{ch}}=A_{2} h_{1}+B_{2} h_{2}=\left(\begin{array}{ll}
m_{\mathrm{e}} & 0  \tag{12}\\
0 & m_{\mu}
\end{array}\right)
$$

$m_{\mathrm{e}}, m_{\mu}$ in eq. (12) are the physical masses of electron and muon respectively.
The 7 gauge bosons corresponding to $\mathrm{SU} 2_{\mathrm{L}} \times \mathrm{SU} 2_{\mathrm{R}} \times(\mathrm{U} 1)_{\mathrm{v}}$ shall be denoted by

$$
\begin{equation*}
\left(\mathrm{W}_{\mu}^{+}\right)_{\mathrm{L}, \mathrm{R}}=\frac{1}{\sqrt{2}}\left(\mathrm{~W}_{\mu}^{1}-\mathrm{i} \mathrm{~W}_{\mu}^{2}\right)_{\mathrm{L}, \mathrm{R}} ; \quad\left(\mathrm{W}_{\mu}^{0}\right)_{\mathrm{L}, \mathrm{R}}=\left(\mathrm{W}_{\mu}^{3}\right)_{\mathrm{L}, \mathrm{R}} ; \mathrm{Y}_{\mu}^{\mathrm{V}} \tag{13}
\end{equation*}
$$

Using the basis of eq. (11) the lepton currents couple to $\left(W_{L, R}, Y_{V}\right)$ conserving parity invariance:

$$
\mathscr{A}=\sum_{k=1}^{2}\left\{\begin{array}{l}
\bar{\ell}^{(k)} \gamma^{\mu} g \frac{\tau}{2}\left[\frac{1+\gamma_{5}}{2} \mathrm{~W}_{\mu}^{\mathrm{L}}+\frac{1-\gamma_{5}}{2} \mathrm{~W}_{\mu}^{\mathrm{R}}\right] \ell^{(k)}  \tag{14}\\
-\frac{g_{\mathrm{V}}}{2} \bar{l}^{(k)} \gamma^{\mu} \mathrm{Y}_{\mu}^{\mathrm{V}_{\ell}(k)}
\end{array}\right\}
$$

In the limit $D \rightarrow \infty$ the above scheme reduces to the $\mathrm{SU} 2_{\mathrm{L}} \times \mathrm{U} 1\left(\mathrm{U} 1 \neq(\mathrm{U} 1)_{\mathrm{V}}\right)$ theory with its symmetry breaking provided by a set of scalar $\operatorname{SU} 2_{L}$-doublets as proposed by Weinberg [3] with the identification

$$
\begin{aligned}
& \sin ^{2} \vartheta_{\mathrm{W}}=\frac{g_{\mathrm{V}}^{2}}{g^{2}+2 g_{\mathrm{V}}^{2}}\left(\leqslant \frac{1}{2}\right) ; \quad \sqrt{4 \pi \alpha}=\mathrm{e}=g \sin \vartheta_{\mathrm{W}}, \\
& \mathrm{Y} \quad=\sin \vartheta_{\mathrm{V}} \mathrm{~W}_{\mathrm{R}}^{0}+\cos \vartheta_{\mathrm{V}} \mathrm{Y}^{\mathrm{V}} \\
& \operatorname{tg} \vartheta_{\mathrm{V}}=\frac{g_{\mathrm{V}}}{g} ; \quad \operatorname{tg} \vartheta_{\mathrm{W}}=\sin \vartheta_{\mathrm{V}} \\
& m_{\mathrm{Z}}^{2}=2\left(g^{2}+g_{\mathrm{V}}^{2}\right) D^{2} \rightarrow \infty
\end{aligned} \rightarrow\left\{\begin{array}{l}
\gamma=\sin \vartheta_{\mathrm{W}} \mathrm{~W}_{\mathrm{L}}^{0}+\cos \vartheta_{\mathrm{W}} \mathrm{Y} \\
\mathrm{Z}=\cos \vartheta_{\mathrm{W}} W_{\mathrm{L}}^{0}-\sin \vartheta_{\mathrm{W}} \mathrm{Y} \\
\left(\mathrm{Z}^{\prime}=\cos \vartheta_{\mathrm{V}} W_{\mathrm{R}}^{0}-\sin \vartheta_{\mathrm{V}} \mathrm{Y}^{\mathrm{V}}\right) .
\end{array}\right.
$$

The mass matrices of the gauge bosons in the neutral and charged sectors are given in terms of the quantities

$$
\begin{equation*}
F^{2}=\frac{1}{2}\left(\left|A_{1}\right|^{2}+\left|A_{2}\right|^{2}+\left|B_{1}\right|^{2}+\left|B_{2}\right|^{2}\right), \quad G=\operatorname{Re}\left(A_{1}^{*} A_{2}+B_{1}^{*} B_{2}\right)=F^{2} \sin \varphi ; \quad D^{2} \tag{16}
\end{equation*}
$$

in the following form

$$
\begin{align*}
& \mathcal{L}_{m_{\mathrm{B}}^{2}}^{\text {neutral }}=\frac{1}{2} g^{2} F^{2}\left(\mathrm{~W}_{\mathrm{L}}^{0}-\mathrm{W}_{\mathrm{R}}^{0}\right)^{2}+D^{2}\left(g \mathrm{~W}_{\mathrm{R}}^{0}-g_{\mathrm{V}} \mathrm{Y}^{\mathrm{V}}\right)^{2}, \\
& \mathcal{L}_{m_{\mathrm{B}}^{\text {charged }}}^{2}=g^{2}\left\{F^{2} \mathrm{~W}_{\mathrm{L}}^{-} \mathrm{W}_{\mathrm{R}}^{+}-G\left(\mathrm{~W}_{\mathrm{L}}^{-} \mathrm{W}_{\mathrm{R}}^{+}+\mathrm{W}_{\mathrm{R}}^{-} \mathrm{W}_{\mathrm{L}}^{+}\right)+\left(F^{2}+D^{2}\right) \mathrm{W}_{\mathrm{R}}^{-} \mathrm{W}_{\mathrm{R}}^{+}\right\} . \tag{17}
\end{align*}
$$

Expanding in powers of $F^{2} / D^{2}$ we obtain the eigenstates of the mass matrix $\nu$ :

$$
\begin{align*}
& \mathrm{Z}_{1} \approx \mathrm{Z}+\xi \mathrm{Z}^{\prime}, \quad Z_{2} \approx \xi \mathrm{Z}+\mathrm{Z}^{\prime},  \tag{18}\\
& m_{\mathrm{Z}_{1}}^{2}=\frac{g^{2} F^{2}}{\cos ^{2} \vartheta_{\mathrm{W}}}\left(1+\mathrm{O}\left(\frac{F^{2}}{D^{2}}\right)\right), \quad m_{Z_{2}}^{2}=\frac{2 g^{2} D^{2}}{1-\operatorname{tg}^{2} \vartheta_{\mathrm{W}}}\left(1+\mathrm{o}\left(\frac{F^{2}}{D^{2}}\right)\right), \quad \xi=\frac{m_{\mathrm{Z}_{1}}^{2}}{m_{\mathrm{Z}_{2}}^{2}}\left(\frac{1-\operatorname{tg}^{2} \varphi_{\mathrm{W}}}{1+\operatorname{tg}^{2} \vartheta_{\mathrm{W}}}\right)^{1 / 2},
\end{align*}
$$

in the neutral sector and

$$
\begin{align*}
& \mathrm{W}_{1}^{+} \approx \mathrm{W}_{\mathrm{L}}^{+}+\eta \mathrm{W}_{\mathrm{R}}^{+} ; \quad \mathrm{W}_{2}^{+} \approx \mathrm{W}_{\mathrm{R}}^{+}-\eta \mathrm{W}_{\mathrm{L}}^{+}, \quad \eta=m_{\mathrm{W}_{1}}^{2} G / m_{\mathrm{W}_{2}}^{2} F^{2}=m_{\mathrm{W}_{1}}^{2} \sin \varphi / m_{\mathrm{W}_{2}}^{2} \\
& m_{\mathrm{W}_{1}^{ \pm}}^{2}=g^{2} F^{2}\left(1+\mathrm{O}\left(F^{2} / D^{2}\right)\right), \quad m_{\mathrm{W}_{3}^{ \pm}}^{2}=g^{2} D^{2}\left(1+\mathrm{O}\left(F^{2} / D^{2}\right)\right), \tag{19}
\end{align*}
$$

and thus $F=\left(4 \sqrt{ } 2 G_{\mathrm{F}}\right)^{-1 / 2} \approx 124 \mathrm{GeV}$.
We note the relation

$$
\begin{equation*}
m_{\mathrm{W}_{1}^{\frac{1}{1}}}^{2} / \cos ^{2} \vartheta_{\mathrm{W}} m_{\mathrm{Z}_{1}}^{2}=1+\mathrm{O}\left(F^{2} / D^{2}\right) \tag{20}
\end{equation*}
$$

which reflects the realization of the doublet breaking mechanısm inherent to $\mathrm{SU} 2_{\mathrm{L}} \times \mathrm{U} 1$ in the limit $F / D \rightarrow 0$.
We now turn to the neutrino mass matrix which contains the lepton number conserving part

$$
\left(\mathscr{M}_{\mathrm{n}}\right)_{i k}=A_{1} h_{1}^{i k}+B_{1} h_{2}^{i k},
$$

and a lepton number violating part

$$
\left(N_{\mathrm{R}}\right)_{i k}=D h_{\mathrm{R}}^{i k}=\left(N_{\mathrm{R}}\right)_{k i}
$$

In the bassis we have chosen $h_{1}, h_{2}$ are constraned by eq. (12) but this does not constrain ( $\mathcal{M}_{\mathrm{n}}$ ).
Combining the CPT-transformed right-handed - with the left-handed fields in eq. (11) we obtain the Majoranalike basis of eq. (2)

$$
\left(\mathrm{f}^{\dot{d}}\right)=\left(\mathrm{f}_{1}^{\dot{\alpha}}, \mathrm{f}_{2}^{\dot{\alpha}}, \widetilde{\mathrm{f}}_{1}^{\dot{\alpha}} \widetilde{\mathrm{f}}_{2}^{\dot{\alpha}}\right)=\left(\nu_{\mathrm{eL}}, \nu_{\mu \mathrm{L}}, \widetilde{\mathrm{~N}}_{\mathrm{eL}}, \widetilde{\mathrm{~N}}_{\mu \mathrm{L}}\right)^{\alpha}, \quad \dot{\alpha}=1,2 .
$$

The mass elgenstates correspond to the solutions of the equation

$$
\begin{equation*}
\left(\mathrm{i}_{0}+\frac{1}{1} \nabla \boldsymbol{\nabla}\right) \mathrm{f}=\mu\left(1 \sigma_{2}\right) \mathrm{f}^{*}, \tag{21}
\end{equation*}
$$

where $\mu$ is the $4 \times 4$ symmetric (complex) matrix of the following $2 \times 2$ block form

$$
\mu=\left(\begin{array}{ll}
0 & m_{\mathrm{n}}  \tag{22}\\
m_{\mathrm{n}}^{\mathrm{T}} & N_{\mathrm{R}}
\end{array}\right)
$$

We assume the strength's of the Yukawa couplings $h_{1}, h_{2}$, are of the same order of magnitude or smaller than $h_{\mathrm{R}}$

$$
\mathrm{O}\left(\left|h_{1}\right|\right)=\mathrm{O}\left(\left|h_{2}\right|\right) \leqslant \mathrm{O}\left(\left|h_{\mathrm{R}}\right|\right), \quad|h|^{2}=\sum_{i, k}\left|h_{i k}\right|^{2} .
$$

It follows

$$
\begin{equation*}
\mathrm{O}\left(\left|\mathcal{m}_{\mathrm{n}}\right|\right)=\mathrm{O}\left(\left|m_{\mathrm{ch}}\right|\right) \leqslant \mathrm{O} \frac{F}{D}|N| \ll|N|, \tag{23}
\end{equation*}
$$

and hence we can dagonalize $\mu$ expanding with respect to $\left|m_{\mathrm{n}}\right| /\left|N_{\mathrm{R}}\right|$.

$$
\begin{align*}
& \mu=v \mu_{\text {diag }} v^{\mathrm{T}} ; \quad v v^{+}=\mathbf{1}, \quad \mathrm{f}=v \mathrm{f}_{(1)}, \quad \mu_{\text {daxg }}=\left(\begin{array}{cccc}
m_{1}^{\nu} & & & \\
& m_{2}^{\nu} & & 0 \\
& 0 & m_{1}^{\mathrm{N}} & \\
& & & m_{2}^{\mathrm{N}}
\end{array}\right) m_{1,2}^{\nu}, m_{1,2}^{\mathrm{N}} \geqslant 0 . \tag{24}
\end{align*}
$$

$$
\begin{equation*}
m_{\nu}=\mathrm{O}\left(\frac{\left|m_{\mathrm{n}}\right|^{2}}{m_{1,2}^{\mathrm{N}}}\right) \lesssim 10 \mathrm{eV} \tag{25}
\end{equation*}
$$

Assuming $m^{\nu} / m_{\mu}=\mathrm{O}\left(10^{-8}\right)$ it follows

$$
\begin{equation*}
\left(10^{4} \frac{\left|m_{\mathrm{n}}\right|}{m_{\mu}}\right)^{2}=\mathrm{O}\left(\frac{m_{\mathrm{N}}}{m_{\mu}}\right), \quad|m|_{\mathrm{n}} \approx m_{\mu} \rightarrow m_{\mathrm{N}} \approx 10^{7} \mathrm{GeV}, \quad|m|_{\mathrm{n}} \approx 10^{-3} m_{\mu} \rightarrow m_{\mathrm{N}} \approx 10 \mathrm{GeV} \tag{26}
\end{equation*}
$$

We proceed to compute and estımate the decay amplitudes for the process $\mu^{-} \rightarrow \mathrm{e}^{-} \gamma$ due to fermion-gauge boson interactions alone.

The corresponding radiation graph [12] yields the following amplitude
${ }^{\neq 6}$ Reducing all four by four matrices to $2 \times 2$ block forms we obtan: $\quad v=\left(\begin{array}{ll}v_{11} & v_{12} \\ v_{21} & v_{22}\end{array}\right): \quad v_{11}\left(\begin{array}{ll}m_{1}^{\nu} & 0 \\ 0 & m_{2}^{\nu}\end{array}\right) v_{11}^{\mathrm{T}} \approx-\mathcal{M _ { \mathrm { n } } N _ { \mathrm { R } } ^ { - 1 } M _ { \mathrm { n } } ^ { \mathrm { T } } , ~}$

$$
v_{22}\left(\begin{array}{ll}
m_{1}^{\mathrm{N}} & 0 \\
0 & m_{2}^{\mathrm{N}}
\end{array}\right) v_{22}^{\mathrm{T}} \approx N_{\mathrm{R}}, \quad v_{12} \approx M_{\mathrm{n}} N_{\mathrm{R}}^{-1} v_{22} ; \quad v_{21} \approx-\left(M_{\mathrm{n}} N_{\mathrm{R}}^{-1}\right)^{+} v_{11} .
$$

Table 1
Order of magnitude of helicity amplitudes in the four cases, I: $m_{\mathrm{N}}<m_{\mathrm{W}_{1}}$, II: $m_{\mathrm{N}} \approx m_{\mathrm{W}_{1}}$, III $m_{\mathrm{N}} \approx m_{\mathrm{W}_{2}}$, IV: $m_{\mathrm{N}} \geqslant m_{\mathrm{W}_{2}}$.

|  | $\left\|T_{\mathrm{LL}}\right\|$ | $\left\|T_{\mathrm{LR}}\right\|=\mathrm{O}\left(\left\|T_{\mathrm{RL}}\right\|\right)$ | $\left\|T_{\mathrm{RR}}\right\|$ |
| :--- | :--- | :--- | :--- |
| I: | $\frac{1}{4} \times 10^{-8} \frac{m_{\mu} m_{\mathrm{N}}}{m_{\mathrm{W}_{1}^{2}}}$ | $\sin \varphi \times 10^{-4}\left(\frac{m_{\mathrm{N}}}{m_{\mu}}\right)^{1 / 2}$ | $\frac{m_{\mathrm{W}_{1}^{2}}}{m_{\mathrm{W}_{2}^{2}}}$ |
| II: | $10^{-8} \frac{m_{\mu}}{m_{\mathrm{W}_{1}}}$ | $\sin \varphi \times 10^{-4}\left(\frac{m_{\mathrm{W}_{1}}}{m_{\mu}}\right)^{1 / 2} \frac{m_{\mathrm{W}_{1}^{2}}}{m_{\mathrm{W}_{2}^{2}}}$ | $\frac{m_{\mathrm{W}_{1}}^{2}}{m_{\mathrm{W}_{2}^{2}}} \frac{m_{\mathrm{N}}^{2}}{m_{\mathrm{W}_{2}^{2}}}$ |
| III: | $\frac{1}{3} \times 10^{-8} \frac{m_{\mu}}{m_{\mathrm{W}_{2}}}$ | $\sin \varphi \times 10^{-4}\left(\frac{m_{\mathrm{W}_{2}}}{m_{\mu}}\right)^{1 / 2} \frac{m_{\mathrm{W}_{1}^{2}}^{2}}{m_{\mathrm{W}_{2}^{2}}}$ | $\frac{1}{4}\left(\frac{m_{\mathrm{W}_{1}}}{m_{\mathrm{W}_{2}}}\right)^{4}$ |

|  |  | $\frac{m_{\mathrm{W}_{1}^{2}}^{2}}{m_{\mathrm{N}}^{2}} \log \left(\frac{m_{\mathrm{N}}^{2}}{m_{\mathrm{W}_{2}^{2}}}\right)$ |  |

$$
\begin{equation*}
T_{\mu \rightarrow \mathrm{e} \gamma}=\frac{1}{m_{\mathrm{W}_{1}}^{2}} \overline{\mathrm{u}}_{\mathrm{e}} \mathrm{i} \sigma_{\alpha \beta} \epsilon_{\gamma}^{\alpha} k_{\gamma}^{\beta} T_{\mathrm{W}} \mathrm{u}_{\mu}, \quad T_{\mathrm{W}}=\frac{e g^{2}}{32 \pi^{2}}\left(A \frac{1-\gamma_{5}}{2}+B \frac{1+\gamma_{5}}{2}\right) . \tag{27}
\end{equation*}
$$

The factor $1 / m_{W_{1}^{2}}^{2}$ in eq. (27) simplifies the comparison with the (main) $\mu^{-} \rightarrow \mathrm{e}^{-} \bar{\nu}_{\mathrm{e}} \nu_{\mu}$ decay.
In the limit $m_{\mathrm{e}} \rightarrow 0$ we obtain

$$
\begin{align*}
& A=\sum_{k}\left(T_{\mathrm{LL}}^{k}+T_{\mathrm{LR}}^{k}\right) ; \quad B=\sum_{k}\left(T_{\mathrm{RR}}^{k}+T_{\mathrm{RL}}^{k}\right)^{\neq 7} \quad k=\left(\nu_{1}, \nu_{2}, \mathrm{~N}_{1}, \mathrm{~N}_{2}\right) \quad\left(m_{\nu_{1}}, m_{\nu_{2}}, m_{\mathrm{N}_{1}}, m_{\mathrm{N}_{2}}\right), \\
& m_{\mathrm{N}}=\operatorname{Max}_{1,2}\left(m_{\mathrm{N}_{1}, 2}\right) \tag{28}
\end{align*}
$$

$k(=1, \ldots, 4)$ in eq. (28) denotes the contribution of a given mass eigenstate in the neutral fermion sector.
We consider four cases, I: $m_{\mathrm{N}} \ll m_{\mathrm{W}_{1}}\left(\ll m_{\mathrm{W}_{2}}\right)$; II: $m_{\mathrm{N}} \approx m_{\mathrm{W}_{1}}$; III: $m_{\mathrm{W}_{1}} \ll m_{\mathrm{N}} \approx m_{\mathrm{W}_{2}}$; IV: $m_{\mathrm{N}} \gg m_{\mathrm{W}_{2}}$.
Within the above limits exact resuits can be obtained in terms of the mass matrix $\mu$ in eq. (24) ${ }^{\neq 7}$. We only give the respective orders of magnitudes of the amplitudes $T_{x y}=\Sigma_{k} T_{x y}^{k}$ here in terms of the parameters $m_{\mathrm{N}_{1}}, m_{\mathrm{W}_{1}}$ $\approx 37.6 \mathrm{GeV} / \sin \vartheta_{\mathrm{W}} \approx 60 \mathrm{GeV}$
$\left|m_{\mathrm{n}}\right| \approx\left(m_{\nu} m_{\mathrm{N}}\right)^{1 / 2} \quad\left(m_{\nu}\right.$ : characteristic neutrino mass $)$.
We assume $m_{\nu} \approx 10^{-8} m_{\mu}$ here $\left(\left|M_{n}\right| \approx 10^{-4}\left(m_{\mu} m_{\mathrm{N}}\right)^{1 / 2}\right)$. The results are given in table 1 .
The branching ratio $B^{\mu \rightarrow \mathrm{e} \gamma}=\Gamma^{\mu \rightarrow \mathrm{e} \mathrm{\gamma}} / \Gamma^{\text {tot }},\left(\Gamma_{\mu}^{\text {tot }} \approx G_{\mathrm{F}}^{2} m_{\mu}^{5} / 192 \pi^{3}\right)$ restricts the possibilities in table 1:
${ }^{\neq 7} T_{x y}^{k}$ in eq. (28) are determined from the mass matrix $\mu$ in eq. (24). $\quad T_{x y}^{k}=\sum_{1,2} c_{x}^{k}(\mathrm{e}) \bar{c}{ }_{y}^{k}(\mu) t_{x y}^{k}\left(m_{\mu}, m_{k} ; m_{\mathrm{W}_{1,2}}\right), \quad c_{\mathrm{L}}^{k}\left(\mathrm{e}^{-}\right)$ $=v_{1 k}, \quad c_{\mathrm{L}}^{k}\left(\mu^{-}\right)=v_{2 k}, \quad c_{\mathrm{R}}^{k}\left(\mathrm{e}^{-}\right)=\bar{v}_{3 k}, \quad c_{\mathrm{R}}^{k}\left(\mu^{-}\right)=\bar{v}_{4 k}, \quad t_{\mathrm{LL}}^{k} \approx t_{\mathrm{LL}}\left(m_{k}, m_{\mathrm{W}_{1}}\right) . \quad t_{\mathrm{LR}}^{k} \approx t_{\mathrm{RL}}^{k} \approx-\eta \frac{m_{k}}{m_{\mu}} t_{\mathrm{LR}}\left(m_{k}, m_{\mathrm{W}_{1}}\right)$, $t_{\mathrm{RR}}^{k} \approx t_{\mathrm{LL}}\left(m_{k}, m_{\mathrm{W}_{2}}\right) ; \quad \eta=\sin \varphi / m_{\mathrm{W}_{2}}^{2}, \quad t_{\mathrm{LL}}(a, b)=2 I_{1}+\frac{a^{2}}{b^{2}}\left(J_{3}-J_{1}\right) ; \quad t_{\mathrm{LR}}(a, b)=4 I_{\mathrm{RL}}+\frac{a^{2}}{b^{2}} J_{3}, \quad\left\{I_{1}, I_{\mathrm{RL}}, J, J_{3}\right\}$ $=I_{\kappa}, \quad \kappa=1, ., 4, \quad I_{\kappa}(a, b)=\int_{0}^{1} \mathrm{~d} x f_{\kappa}(x) \frac{m_{\mathrm{W}_{1}}^{2}}{F} ; \quad F(a, b ; x)=(1-x) b^{2}+x a^{2}, \quad f\left(I_{1}\right)=(1-x)^{2}\left(1-\frac{1}{2} x\right), \quad f\left(I_{\mathrm{RL}}\right)=(1-x)^{2}$ $f\left(J_{1}\right)=\frac{1}{2} x(1-x)^{2}, \quad f\left(J_{3}\right)=x(1-x)$.

$$
\begin{equation*}
\frac{2 \pi}{3 \alpha} B^{\mu \rightarrow \mathrm{e} \gamma}=\left(|A|^{2}+|B|^{2}\right) ; \quad A=T_{\mathrm{LL}}+T_{\mathrm{LR}}, \quad B=T_{\mathrm{RR}}+T_{\mathrm{RL}} \tag{29}
\end{equation*}
$$

If $B^{\mu \rightarrow \mathrm{e} \gamma}=\mathrm{O}\left(10^{-9}\right)$ then $\operatorname{Max}(|A|,|B|)=\mathrm{O}\left(5 \times 10^{-4}\right)$. This excludes $T_{\mathrm{LL}}$ grom giving a sizable contribution.
For $T_{\mathrm{LR}}, T_{\mathrm{RL}}$ I-III would imply $\sin \varphi\left(m_{\mathrm{W}_{1}} / m_{\mathrm{W}_{2}}\right)^{2} \approx(0.1-0.2)$ and thus considerable deviation of the lepton current from the $\mathrm{V}-\mathrm{A}$ structure. We conclude that $T_{\mathrm{LR}}, T_{\mathrm{RL}}$ cannot contribute significantly (always for $B^{\mu \rightarrow \mathrm{e} \gamma}$ $\approx 10^{-9}$ ) unless $m_{\mathrm{N}} \gg m_{\mathrm{W}_{2}}$ (e.g. $\sin \varphi m_{\mathrm{W}^{2}} / m_{\mathrm{W}_{2}^{2}}=10^{-2} \rightarrow m_{\mathrm{N}} \approx 2 \times 10^{4} \mathrm{GeV}$ ).

Finally $T_{\mathrm{RR}}$ can be a source of $\mu \rightarrow \mathrm{e} \gamma$ decay at the above level in cases III and IV provided $m_{\mathrm{N}} \leqslant 10 m_{\mathrm{W}_{2}}$.
In conclusion we remark that III is an outstanding possibility (unless $B^{\mu \rightarrow \mathrm{e} \gamma} \leqslant 10^{-9}$ ), yielding the parameters

$$
m_{\mathrm{N}} \approx m_{\mathrm{W}_{2}} \approx 45 m_{\mathrm{W}_{1}} \approx 2700 \mathrm{GeV}{ }^{\ddagger 8}, \quad\left|T_{\mathrm{LL}}\right|,\left|T_{\mathrm{LR}}\right|,\left|T_{\mathrm{RL}}\right| \ll\left|T_{\mathrm{RR}}\right|
$$

The $\mu \rightarrow 3$ e decay corresponds in all cases considered here, mainly to ordinary Dalitz pairs.
A dominating $T_{\mathrm{RR}}$ amplitude would produce predominantly right-handed $\mathrm{e}^{-}$from $\mu^{-} \rightarrow \mathrm{e}^{-} \gamma$ decay $\left(\mathbf{P}_{\text {long }}\left(\mathrm{e}^{-}\right)\right.$ $\left.=+v_{\mathrm{e}}-/ / c\right)$ and no $T$-violating polarization of $\mathrm{e}^{-}$perpendicular to the plane spanned by the spin of $\mu^{-}$and the momentum of $\mathrm{e}^{-}$. This polarization could be large provided $\left|T_{\mathrm{RL}}\right|,\left|T_{\mathrm{LR}}\right|=\mathrm{O}\left(\left|T_{\mathrm{RR}}\right|\right)$. ${ }^{\ddagger 9}$

It is a pleasure to thank H. Fritzsch, T.P. Cheng, S.P. Rosen, C. Petitjean and H. Leutwyler for valuable discussions.
$\not{ }^{8}$ The Majorana leptons $N$ couple to $e^{-}$and thus produce neutrinoless double $\beta$-decay. However, their coupling constant is reduced relative to the Fermı constant by a factor $\left(m_{\mathrm{W}_{1}} / m_{\mathrm{W}_{2}}\right)^{2} \approx 1 / 2 \times 10^{-3}$. This together with $m_{\mathrm{N}} \approx m_{\mathrm{W}_{2}}$ insures an effect small enough to be compatible with observation [13].
${ }^{\ddagger 9}$ The asymmetry parameters of the $\mu^{-} \rightarrow \mathrm{e}^{-} \gamma$ decay are $\vartheta=\vartheta\left(\boldsymbol{P}_{\mathrm{e}^{-}}, \boldsymbol{S}_{\mu}\right), \quad \frac{1}{\Gamma_{\mu \rightarrow \mathrm{e}^{-} \gamma}} \frac{\mathrm{d} \Gamma}{\mathrm{d} \cos \vartheta}=\frac{1}{2}\left(1+\mathbf{P}_{\mu}-a \cos \vartheta\right)$,

$$
\begin{array}{ll}
a=\frac{|A|^{2}-|B|^{2}}{|A|^{2}+|B|^{2}}, & \frac{\mathrm{~d}\left[\Gamma \operatorname{Det}\left(S_{\mathrm{e}^{-}, S_{\mu}-,} \frac{\mathbf{P}_{\mathrm{e}}}{\mathbf{P}_{\mathrm{e}} \mid}\right)\right] / \mathrm{d} \cos \vartheta}{\mathrm{~d} / \mathrm{d} \cos \vartheta}=\mathbf{P}_{\mu^{-}} \frac{\sin \vartheta}{1+\mathbf{P}_{\mu}-a \cos \vartheta} \frac{2 \operatorname{Im} \bar{A} B}{|A|^{2}+|B|^{2}}, \quad C P T \mathrm{e}^{-} \rightarrow \mathrm{e}^{+}, \mu^{-} \rightarrow \mu^{+}, \\
1 \pm \gamma_{5} \rightarrow 1 \mp \gamma_{5}, & A \rightarrow+\bar{B}, B \rightarrow \bar{A}, \quad \quad \mathbf{P}_{\mu^{-}} \text {degree of polarization of the stopped muon. }
\end{array}
$$

[^0]:    $\not{ }^{\ddagger 1}$ In the hght of the present discussion we note that the vectorlike scheme of ref [1] is unable to correlate points (1)-(iv). It is also at variance with the inclusive neutrino-hadron (isoscalar target) cross section ratio
     $=0.4 \pm 0.2$ HPWF [2].
    $\not{ }^{2}$ The experıment currently in progress at SIN looking for the decay $\mu^{+} \rightarrow \mathrm{e}^{+} \gamma$ exploiting the high intensity muon beam has triggered a renewed discussion of possible sources of lepton number violations [7]. We should like to stress that we take the rumors of a positive signal as stimulus for the present investigation only.

[^1]:    ${ }^{\ddagger 3}$ The relation between Majorana and chiral fields is. $\psi_{1,2}^{(k)}=R_{1,2}^{(k)} ; \quad \psi_{3,4}^{(k)}=J_{1,2}^{(k)}, \quad R_{1,2}^{(k)}=\ell_{k L}^{i, \dot{L}}+$ h.c., $J_{1,2}^{(k)}=(1 / \mathrm{i}) \ell_{k \mathrm{~L}}^{1, i}+$ h.c.
    ${ }^{4}$ Extending $\mathrm{Y}_{\mathrm{V}}$ to quarks. $\left(Y_{\mathrm{V}}(q)=\frac{1}{3}, Y_{\mathrm{V}}(q)=-\frac{1}{3}\right) \mathrm{I}_{1,2} \mathrm{mplies} Y_{\mathrm{V}}=A-L$, where $A$ denotes baryon number and $L=L_{\mathrm{e}}+L_{\mu}+$ (overall) lepton number. Thus $Y_{V}$ is conserved if baryon and lepton numbers are separately conserved, and yet there does not exist a long range force associated with the corresponding boson. This problem generally arises in unified gauge theories [9].
    $\ddagger^{5}$ We do not include for simplicity an eventual third lepton multiplet including the heavy charged lepton which may have been observed in the $\mathrm{e}^{+} \mathrm{e}^{-} \rightarrow \mathrm{e}^{-} \mu^{+} \mathrm{X}$ events at Spear [11] involving no (detected) hadron in the field state.
